The language is very simple, just selecting a couple of elements to create them, as in other programs, but the syntax of VisualDB is based on SQL and the database schema is generated by inserting columns and relations between them. So, even a person with no knowledge of databases can easily grasp the command and structure of VisualDB. Allows you to take a fast look at the database The most important feature of VisualDB is that it allows you to take a quick glance at the database as the schema diagram to see all the details. You can see if there are any columns that are not used, or if there are constraints that are not satisfied. It is very easy to see where to add, remove, or modify columns or relations. The VisualEditor makes your work faster VisualEditor is an easy-to-use tool that allows you to create and save diagrams for the database quickly and efficiently. This tool is very useful for working with large databases. These features allow users to do things such as disable keystrokes, use public/private key encryption, and even make tunneling connections over SSH easier. While these features can be very useful, they also have a significant number of security issues associated with them. One such security vulnerability is the ability to disable the default RSA authentication mechanism for SSH. What's New In VisualDB?

- Database schema recognition based on database metadata. - Visualized relations between tables and view diagrams. - Properties of columns and tables. - Import and export of database files. - Data analysis and search. VisualDB has been developed by Sebastien Jaud and Matthias Meier and you can learn more about the project on the VisualDB website. VisualDB Website VisualDB Github Install VisualDB VisualDB is currently in development, so we have not developed binaries for all of our releases. You should first download the source code and compile the project from source. VisualDB is written in C++. To build VisualDB you will need a C++ compiler (gcc, g++ or Visual C++). VisualDB uses boost for the needed features and is open-source. You can find the boost download page here. We recommend you download the binary package for Debian GNU/Linux, as it contains the GNU C++ compiler. VisualDB is compatible with Linux operating systems. VisualDB is a small application, so it doesn't take a lot of resources. To use VisualDB on a system with lower RAM, just set the environment variable "VDBCONFIG_SIZE". For example, on Debian or Ubuntu systems: \$ export VDBCONFIG_SIZE=128 Now you should be able to run VisualDB. You can find the command to run VisualDB on each platform on the VisualDB user guide. VisualDB CLI VisualDB also supports the VisualDB CLI, which can be used to visualize the database schema in a browser. For example, you can open a console, type in the command "visualdb" and then a browser opens up with a visualized schema of your database. Getting started with VisualDB CLI 1) Start VisualDB CLI on your computer 2) Start the database with the "visualdb" command If VisualDB doesn't start automatically, you have to make sure the "visualdb" command is in your path. You can find the path to your PATH environment variable on the ~/.bash_profile file. The command to start VisualDB with the CLI is: \$ visualdb 3) Start the database using the URL of your choice If you want to use a browser instead of VisualDB CLI, you have to give VisualDB a URL for the visualization. VisualDB can be run with a URL, like or any other valid URL. When VisualDB runs from a URL, it will open up a graphical GUI to select a database file. There is no need to download the database file to your computer first. You can also download a database file that VisualDB can open and use it to start VisualDB
